

(a) PCA of 16 sampled chunks, one state looks bimodal: separation 128 (chance level 3.9)

(b) same 16 samples, gripper channel identical action, one step apart in time

(c) separation at every probed state vs chance GR1 within chance; $\pi_{0.5}$ has a tail

(d) $\pi_{0.5}$: every split beyond the null's range is gripper timing, not an alternative action
